5. Statistics, Data science, and Probability
Review: Probability and randomness

Start of transcript. Skip to the end.

OK.

So going back to what I said, there's a bunch of words

that you've heard that are sort of related.

You're probably not here because you

want to do 1970s statistics.

You want to do machine learning.

You want to do data science.

You want to do artificial intelligence.

Probability review: dice rolling game

1/1 point (graded)

Alice and Bob play a game where two fair six-sided dice are rolled.

Alice gets $1 if the sum of the numbers of the two dice is a prime number. (The number 1 is not prime.)

Bob gets $3 if the numbers on the two dice are the same (e.g. 1-1, 2-2, ...).

Who makes more money on average (i.e. in expectation)?

- Alice
- Bob
- It does not matter.
- Not enough information to decide.

✔

Solution:

The set of possible outcomes is $\{2,3,4,5,6,7,8,9,10,11,12\}$, of which the prime numbers are $\{2,3,5,7,11\}$. Bob wins $3 whenever he sees one of six outcomes, out of a total of 36. This means he will earn $\frac{6}{36} \times 3 = \frac{1}{2}$ dollars per game in expectation. On the other hand, Alice wins $1 when she sees one of fifteen outcomes. Be careful here, because there are multiple ways for two six-sided dice to sum to 3,5,7 or 11 (As opposed to 2, for which there is only one possible roll). Therefore, Alice wins $1 \times \frac{15}{36}$ dollars in expectation.

Overall, Bob makes more money on average.
