

18.650 – Fundamentals of Statistics

2. Foundations of Inference

Goals

In this unit, we introduce a mathematical formalization of statistical modeling to make a principled sense of the **Trinity of statistical inference**.

We will make sense of the following statements:

1. Estimation:

" $\hat{p} = \bar{R}_n$ is an estimator for the proportion p of couples that turn their head to the right"

(side question: is 64.5% also an estimator for p ?)

2. Confidence intervals:

" $[0.56, 0.73]$ is a 95% confidence interval for p "

3. Hypothesis testing:

"We find statistical evidence that more couples turn their head to the right when kissing"

The rationale behind statistical modeling

- ▶ Let X_1, \dots, X_n be n independent copies of X .
- ▶ The goal of statistics is to learn the distribution of X .
- ▶ If $X \in \{0, 1\}$, easy! It's θ and we only have to learn the parameter
- ▶ Can be more complicated. For example, here is a (partial) dataset with number of siblings (including self) that were collected from college students a few years back: 2, 3, 2, 4, 1, 3, 1, 1, 1, 1, 1, 2, 2, 3, 2, 2, 2, 3, 2, 1, 3, 1, 2, 3, ...
- ▶ We could make no assumption and try to learn the pmf:

| x | 1 | 2 | 3 | 4 | 5 | 6 | ≥ 7 |
|---------------------|-------|-------|-------|-------|-------|-------|-----------------------|
| $\mathbb{P}(X = x)$ | p_1 | p_2 | p_3 | p_4 | p_5 | p_6 | $\sum_{i \geq 7} p_i$ |

That's 7 parameters to learn.

- ▶ Or we could assume that $X - 1 \sim \text{Poisson}(\theta)$. That's 1 parameter to learn!

Statistical model

Formal definition

Let the observed outcome of a statistical experiment be a X_1, \dots, X_n of n i.i.d. random variables in some measurable space E (usually $E \subseteq \mathbb{R}$) and denote by \mathbb{P} their common distribution. A statistical model associated to that statistical experiment is a pair

$$(E, (\mathbb{P}_\theta)_{\theta \in \Theta}),$$

where:

- ▶ E is called the sample space;
- ▶ $(\mathbb{P}_\theta)_{\theta \in \Theta}$ is a family of probability measures on E ;
- ▶ Θ is any set, called the parameter space.

Parametric, nonparametric and semiparametric models

- ▶ Usually, we will assume that the statistical model is *well specified*, i.e., defined such that $P_\theta \in \mathcal{P}$.
- ▶ This particular θ is called the *parameter of interest*, and is unknown: The aim of the statistical experiment is to estimate θ , or check it's properties when they have a special meaning ($\theta > 2?$, $\theta \neq 1/2?$, ...)
- ▶ We often assume that $\Theta \subseteq \mathbb{R}^d$ for some $d \geq 1$: The model is called *parametric*.
- ▶ Sometime we could have Θ be infinite dimensional in which case the model is called *nonparametric*.
- ▶ If $\Theta = \Theta_1 \times \Theta_2$, where Θ_1 is finite dimensional and Θ_2 is infinite dimensional: *semiparametric* model. In these models we only care to estimate the finite dimensional parameter and the infinite dimensional one is called *nuisance* parameter. We will not cover such models in this class.

Examples of parametric models

1. For n Bernoulli trials:

$$\left(\quad , (\text{Ber}(p))_{p \in (0,1)} \right).$$

2. If $X_1, \dots, X_n \stackrel{iid}{\sim} \text{Pois}(\lambda)$ for some unknown $\lambda > 0$,

$$\left(\quad , \quad \right).$$

3. If $X_1, \dots, X_n \stackrel{iid}{\sim} \mathcal{N}(\mu, \sigma^2)$, for some unknown $\mu \in \mathbb{R}$ and $\sigma^2 > 0$:

$$\left(\quad , (\mathcal{N}(\mu, \sigma^2))_{(\mu, \sigma^2) \in \quad} \right).$$

4. If $X_1, \dots, X_n \stackrel{iid}{\sim} \mathcal{N}_d(\mu, I_d)$, for some unknown $\mu \in \mathbb{R}^d$:

$$\left(\quad , (\mathcal{N}_d(\mu, I_d))_{(\mu \in \quad)} \right).$$

Examples of nonparametric models

1. If $X_1, \dots, X_n \in \mathbb{R}$ are i.i.d with unknown *unimodal*¹ pdf f :

$$E =$$

$$\Theta =$$

$$\mathbb{P}_\theta$$

2. If $X_1, \dots, X_n \in \mathbb{R}$ are i.i.d with unknown pdf **1-Lipschitz** pdf f , i.e.

for all $x, y \in \mathbb{R}$.

3. If $X_1, \dots, X_n \in [0, 1]$ are i.i.d with unknown invertible cdf F .

¹Increases on $(-\infty, a)$ and then decreases on (a, ∞) for some $a > 0$.

Further examples

Sometimes we do not have simple notation to write $(\mathbb{P}_\theta)_{\theta \in \Theta}$, e.g., $(\text{Ber}(p))_{p \in (0,1)}$ and we have to be more explicit:

1. Linear regression model: If

$(X_1, Y_1), \dots, (X_n, Y_n) \in \mathbb{R}^d \times \mathbb{R}$ are i.i.d from the linear regression model $Y_i = \beta^\top X_i + \varepsilon_i$ $\varepsilon_i \stackrel{iid}{\sim} \mathcal{N}(0, 1)$ for an unknown $\beta \in \mathbb{R}^d$ and $X_i \sim \mathcal{N}_d(0, I_d)$ independent of ε_i

$$E =$$

$$\Theta =$$

$$\mathbb{P}_\theta$$

2. Cox proportional Hazard model: If

$(X_1, Y_1), \dots, (X_n, Y_n) \in \mathbb{R}^d \times \mathbb{R}$: the conditional distribution of Y given $X = x$ has CDF F of the form

$$F(t) = 1 - \exp \left(- \int_0^t h(u) e^{(\beta^\top x)} du \right)$$

where h is an unknown non-negative nuisance function and $\beta \in \mathbb{R}^d$ is the parameter of interest.

Identifiability

The parameter θ is called *identifiable* iff the map $\theta \in \Theta \mapsto \mathbb{P}_\theta$ is injective, i.e.,

$$\theta \neq \theta' \Rightarrow$$

or equivalently:

$$\mathbb{P}_\theta = \mathbb{P}_{\theta'} \Rightarrow$$

Examples

1. In all four previous examples, the parameter is identifiable.
2. If $X_i = \mathbb{I}_{Y_i \geq 0}$ (indicator function), $Y_1, \dots, Y_n \stackrel{iid}{\sim} \mathcal{N}(\mu, \sigma^2)$, for some unknown $\mu \in \mathbb{R}$ and $\sigma^2 > 0$, are unobserved: μ and σ^2 are not identifiable (but $\theta = \mu/\sigma$ is).

Exercises

a) Which of the following is a statistical model?

1. $(\{1\}, (\text{Ber}(p))_{p \in (0,1)})$
2. $(\{0, 1\}, (\text{Ber}(p))_{p \in (0.2, 0.4)})$
3. Both 1 and 2
4. None of the above

b) Let $X_1, \dots, X_n \stackrel{iid}{\sim} \mathcal{U}([0, a])$ for some unknown $a > 0$. Which one of the following is the associated statistical model?

1. $([0, a], (\mathcal{U}([0, a]))_{a > 0})$
2. $(\mathbb{R}_+, (\mathcal{U}([0, a]))_{a > 0})$
3. $(\mathbb{R}, (\mathcal{U}([0, a]))_{a > 0})$
4. None of the above

Exercises

c) Let $X_i = Y_i^2$, where $Y_1, \dots, Y_n \stackrel{iid}{\sim} \mathcal{U}([0, a])$, for some unknown a , are unobserved. Is a identifiable?

1. Yes
2. No

d) Let $X_i = \mathbb{I}_{Y_i \geq \frac{a}{2}}$, where $Y_1, \dots, Y_n \stackrel{iid}{\sim} \mathcal{U}([0, a])$, for some unknown a , are unobserved. Is a identifiable?

1. Yes
2. No

Estimation

Parameter estimation

- ▶ *Statistic*: Any measurable² function of the sample, e.g., $\bar{X}_n, \max_i X_i, \dots$, sample variance, etc...
- ▶ *Estimator* of θ : Any statistic whose expression does not depend on
- ▶ An estimator $\hat{\theta}_n$ of θ is *weakly* (resp. *strongly*) if

$$\hat{\theta}_n \xrightarrow[n \rightarrow \infty]{\text{P (resp. a.s.)}} \theta \quad (\text{w.r.t. } \mathbb{P}_\theta).$$

- ▶ An estimator $\hat{\theta}_n$ of θ is *asymptotically normal* if

$$\sqrt{n}(\hat{\theta}_n - \theta) \xrightarrow[n \rightarrow \infty]{(d)}$$

The quantity σ^2 is then called *asymptotic*

²Rule of thumb: if you can compute it exactly once given data, it is measurable. You may have some issues with things that are implicitly defined such as sup or inf but not in this class

Bias of an estimator

- Bias of an estimator $\hat{\theta}_n$ of θ :

$$\text{bias}(\hat{\theta}_n) =$$

- If $\text{bias}(\hat{\theta}) = 0$, we say that $\hat{\theta}$ is
- Example: Assume that $X_1, \dots, X_n \stackrel{iid}{\sim} \text{Ber}(p)$ and consider the following estimators for p :

- $\hat{p}_n = \bar{X}_n$: $\text{bias}(\hat{p}_n) =$

- $\hat{p}_n = X_1$: $\text{bias}(\hat{p}_n) =$

- $\hat{p}_n = \frac{X_1 + X_2}{2}$: $\text{bias}(\hat{p}_n) =$

- $\hat{p}_n = \sqrt{\mathbb{I}(X_1 = 1, X_2 = 2)}$

Variance of an estimator

An estimator is a random variable so we can compute its variance.
In the previous examples:

► $\hat{p}_n = \bar{X}_n$: $\text{var}(\hat{p}_n) =$

► $\hat{p}_n = X_1$: $\text{var}(\hat{p}_n) =$

► $\hat{p}_n = \frac{X_1 + X_2}{2}$: $\text{var}(\hat{p}_n) =$

► $\hat{p}_n = \sqrt{\mathbb{I}(X_1 = 1, X_2 = 2)}$

Quadratic risk

- ▶ We want estimators to have low bias and low variance at the same time.
- ▶ The *Risk* (or *quadratic risk*) of an estimator $\hat{\theta}_n \in \mathbb{R}$ is

$$R(\hat{\theta}_n) = \mathbb{E} \left[|\hat{\theta}_n - \theta|^2 \right]$$

- ▶ Low quadratic risk means that both bias and variance are small:
quadratic risk=

Exercises

Let X_1, X_2, \dots, X_n be a random sample from $\mathcal{U}([a, a + 1])$.

- a) Find $\mathbb{E}[\bar{X}_n]$
- b) Is $\bar{X}_n - \frac{1}{2}$ an unbiased estimator for a ?
- c) Find the variance of $\bar{X}_n - \frac{1}{2}$.
- d) Find the quadratic risk of $\bar{X}_n - \frac{1}{2}$.

Confidence intervals

Confidence intervals

Let $(E, (\mathbb{P}_\theta)_{\theta \in \Theta})$ be a statistical model based on observations X_1, \dots, X_n , and assume $\Theta \subseteq \mathbb{R}$. Let $\alpha \in (0, 1)$.

- *Confidence interval (C.I.) of level $1 - \alpha$ for θ* : Any random (depending on X_1, \dots, X_n) interval \mathcal{I} whose boundaries do not depend on θ and such that³:

$$\mathbb{P}_\theta [\mathcal{I} \ni \theta] \geq 1 - \alpha, \quad \forall \theta \in \Theta.$$

- *C.I. of asymptotic level $1 - \alpha$ for θ* : Any random interval \mathcal{I} whose boundaries do not depend on θ and such that:

$$\mathbb{P}_\theta [\mathcal{I} \ni \theta] \geq 1 - \alpha, \quad \forall \theta \in \Theta.$$

³ $\mathcal{I} \ni \theta$ means that \mathcal{I} contains θ . This notation emphasizes the randomness of \mathcal{I} but we can equivalently write $\theta \in \mathcal{I}$.

A confidence interval for the kiss example

- ▶ Recall that we observe $R_1, \dots, R_n \stackrel{iid}{\sim} \text{Ber}(p)$ for some unknown $p \in (0, 1)$.
- ▶ Statistical model: $\left(\{0, 1\}, (\text{Ber}(p))_{p \in (0, 1)}\right)$.
- ▶ Recall that our estimator for p is $\hat{p} = \bar{R}_n$.
- ▶ From CLT:

$$\sqrt{n} \frac{\bar{R}_n - p}{\sqrt{p(1-p)}} \xrightarrow[n \rightarrow \infty]{(d)} \mathcal{N}(0, 1)$$

This means (precisely) that:

- ▶ $\Phi(x)$: cdf of $\mathcal{N}(0, 1)$; $\Phi_n(x)$: cdf of $\sqrt{n} \frac{\bar{R}_n - p}{\sqrt{p(1-p)}}$.
- ▶ Then: $\Phi_n(x) \approx \Phi(x)$ (CLT) when n becomes large. Hence, for all $x > 0$,

$$\mathbb{P} [|\bar{R}_n - p| \geq x] \simeq 2 \left(1 - \Phi \left(\frac{x\sqrt{n}}{\sqrt{p(1-p)}} \right) \right).$$

Confidence interval?

- For a fixed $\alpha \in (0, 1)$, if $q_{\alpha/2}$ is the $(1 - \alpha/2)$ -quantile of $\mathcal{N}(0, 1)$, then with probability $\simeq 1 - \alpha$ (if n is large enough !),

$$\bar{R}_n \in \left[p - \frac{q_{\alpha/2} \sqrt{p(1-p)}}{\sqrt{n}}, p + \frac{q_{\alpha/2} \sqrt{p(1-p)}}{\sqrt{n}} \right].$$

- More precisely

$$\mathbb{P} \left(\left[\bar{R}_n - \frac{q_{\alpha/2} \sqrt{p(1-p)}}{\sqrt{n}}, \bar{R}_n + \frac{q_{\alpha/2} \sqrt{p(1-p)}}{\sqrt{n}} \right] \ni p \right)$$

- But this is **not** a confidence interval because
- To fix this, there are 3 solutions.

Solution 1: Conservative bound

- Note that no matter the (unknown) value of p ,

$$p(1-p) \leq$$

- Hence, asymptotically with probability at least $1 - \alpha$,

$$\bar{R}_n \in \left[p - \frac{q_{\alpha/2}}{2\sqrt{n}}, p + \frac{q_{\alpha/2}}{2\sqrt{n}} \right].$$

- We get the asymptotic confidence interval:

$$\mathcal{I}_{\text{conserv}} = \left[\bar{R}_n - \frac{q_{\alpha/2}}{2\sqrt{n}}, \bar{R}_n + \frac{q_{\alpha/2}}{2\sqrt{n}} \right]$$

- Indeed

$$\lim_{n \rightarrow \infty} \mathbb{P}(\mathcal{I}_{\text{conserv}} \ni p)$$

Solution 2: Solving the (quadratic) equation for p

- ▶ We have the system of two inequalities in p :

$$\bar{R}_n - \frac{q_{\alpha/2} \sqrt{p(1-p)}}{\sqrt{n}} \leq p \leq \bar{R}_n + \frac{q_{\alpha/2} \sqrt{p(1-p)}}{\sqrt{n}}$$

- ▶ Each is a quadratic inequality in p of the form

$$(p - \bar{R}_n)^2 \leq \frac{q_{\alpha/2}^2 p(1-p)}{n}$$

We need to find the roots $p_1 < p_2$ of

$$\left(1 + \frac{q_{\alpha/2}^2}{n}\right)p^2 - \left(2\bar{R}_n + \frac{q_{\alpha/2}^2}{n}\bar{R}_n\right)p + \bar{R}_n^2 = 0$$

- ▶ This leads to a new confidence interval $\mathcal{I}_{\text{solve}} = [p_1, p_2]$ such that:

$$\lim_{n \rightarrow \infty} \mathbb{P}(\mathcal{I}_{\text{solve}} \ni p)$$

(it's complicated to write in generic way so let us wait to have values for n, α and \bar{R}_n to plug-in)

Solution 3: plug-in

- ▶ Recall that by the LLN $\hat{p} = \bar{R}_n \xrightarrow[n \rightarrow \infty]{\mathbb{P}, \text{a.s.}} p$
- ▶ So by Slutsky, we also have

$$\sqrt{n} \frac{\bar{R}_n - p}{\sqrt{p(1-p)}} = \xrightarrow[n \rightarrow \infty]{(d)}$$

- ▶ This leads to a new confidence interval:

$$\mathcal{I}_{\text{plug-in}} = \left[\bar{R}_n - \frac{q_{\alpha/2} \sqrt{\hat{p}(1-\hat{p})}}{\sqrt{n}}, \bar{R}_n + \frac{q_{\alpha/2} \sqrt{\hat{p}(1-\hat{p})}}{\sqrt{n}} \right]$$

such that

$$\lim_{n \rightarrow \infty} \mathbb{P}(\mathcal{I}_{\text{plug-in}} \ni p)$$

95% asymptotic CI for the kiss example

Recall that in the kiss example we had $n = 124$ and $\bar{R}_n = 0.645$.

Assume $\alpha = 5\%$.

For $\mathcal{I}_{\text{solve}}$, we have to find the roots of:

$$1.03p^2 - 1.32p + 0.41 = 0 \quad p_1 = 0.53, p_2 = 0.75$$

We get the following confidence intervals of asymptotic level 95%:

▶ $\mathcal{I}_{\text{conserv}} = [0.56, 0.73]$

▶ $\mathcal{I}_{\text{solve}} = [0.53, 0.75]$

▶ $\mathcal{I}_{\text{plug-in}} = [0.56, 0.73]$

There are many⁴ other possibilities in softwares even ones that use the exact distribution of $n\bar{R}_n \sim$

$$\mathcal{I}_{\text{R default}} = [0.55, 0.73]$$

⁴See R. Newcombe (1998). *Two-Sided Confidence Intervals for the Single Proportion: Comparison of Seven Methods*.

Exercises

a) Let I , J be some 95% and 98% asymptotic confidence intervals (respectively) for p . Which one of the following statements is correct?

1. We always have $I \subset J$.
2. We always have $J \subset I$.
3. None of the above.

b) Find a 98% asymptotic confidence interval for p .

Exercises

c) Consider a new experiment in which there are 150 participants, 75 turned left and 75 turned right. Which of the following is the correct answer?

1. $[0, 0.5]$ is a 50% asymptotic confidence intervals for p
2. $[0.5, 1]$ is a 50% asymptotic confidence intervals for p
3. $[0.466, 0.533]$ is a 50% asymptotic confidence intervals for p
4. $[0.48, 0.52]$ is a 50% asymptotic confidence intervals for p
5. both (1) and (2)
6. (1), (2) and (3)
7. (1), (2), (3) and (4)

Exercises

d) If $[0.34, 0.57]$ is a 95% confidence interval for an unknown proportion p , then the probability that $p \in [0.34, 0.57]$ is

1. 0.025
2. 0.05
3. 0.95
4. None of the above

e) If $[0.34, 0.57]$ is a 95% confidence interval for an unknown proportion p , is it also a 98% confidence interval?

1. Yes
2. No

f) If $[0.34, 0.57]$ is a 95% confidence interval for an unknown proportion p , is it also a 90% confidence interval?

1. Yes
2. No

Another example: The T

Statistical problem

- ▶ You observe the times (in minutes) between arrivals of the T at Kendall: T_1, \dots, T_n .
- ▶ You **assume** that these times are:
 - ▶ Mutually independent
 - ▶ Exponential random variables with common parameter
- ▶ You want to *estimate* the value of λ , based on the observed arrival times.

Discussion of the modeling assumptions

- ▶ Mutual independence of T_1, \dots, T_n : plausible but not completely justified (often the case with independence).
- ▶ T_1, \dots, T_n are exponential r.v.: **lack of memory** of the exponential distribution:

$$\mathbb{P}[T_1 > t + s | T_1 > t] = \mathbb{P}[T_1 > s], \quad \forall s, t \geq 0.$$

Also, $T_i > 0$ almost surely!

- ▶ The exponential distributions of T_1, \dots, T_n have the same parameter: in average all the same inter-arrival time. True only for limited period (rush hour \neq 11pm).

Estimator

- Density of T_1 :

$$f(t) = \lambda e^{-\lambda t}, \quad \forall t \geq 0.$$

- $\mathbb{E}[T_1] = \frac{1}{\lambda}$.

- Hence, a natural estimate of $\frac{1}{\lambda}$ is

$$\bar{T}_n := \frac{1}{n} \sum_{i=1}^n T_i.$$

- A natural estimator of λ is

$$\hat{\lambda} :=$$

First properties

- By the LLN's,

$$\bar{T}_n \xrightarrow[n \rightarrow \infty]{\text{a.s./}\mathbf{P}} \frac{1}{\lambda}$$

- Hence,

$$\hat{\lambda} \xrightarrow[n \rightarrow \infty]{\text{a.s./}\mathbf{P}} \lambda.$$

- By the CLT,

$$\sqrt{n} \left(\bar{T}_n - \frac{1}{\lambda} \right) \xrightarrow[n \rightarrow \infty]{} \mathcal{N}(0, \lambda^{-2}).$$

- How does the CLT transfer to $\hat{\lambda}$? How to find an asymptotic confidence interval for λ ?

The Delta method

Let Z_n be a sequence of random variables such that

$$\sqrt{n}(Z_n - \theta) \xrightarrow[n \rightarrow \infty]{(d)}$$

for some $\theta \in \mathbb{R}$ and $\sigma^2 > 0$ (asymptotically normal).

Let $g : \mathbb{R} \rightarrow \mathbb{R}$ be continuously differentiable at the point θ .
Then,

- ▶ $g(Z_n) \xrightarrow[n \rightarrow \infty]{\mathbb{P}}$
- ▶ $(g(Z_n))_{n \geq 1}$ is also asymptotically normal;
- ▶ More precisely,

$$\sqrt{n}(g(Z_n) - g(\theta)) \xrightarrow[n \rightarrow \infty]{(d)} \mathcal{N}(0, \sigma^2).$$

Consequence of the Delta method

- ▶ $\sqrt{n} \left(\hat{\lambda} - \lambda \right) \xrightarrow[n \rightarrow \infty]{(d)} \mathcal{N}(0, \lambda^2).$
- ▶ Hence, for $\alpha \in (0, 1)$ and when n is large enough,

$$|\hat{\lambda} - \lambda| \leq$$

with probability approximately $1 - \alpha$.

- ▶ Can $\left[\hat{\lambda} - \frac{q_{\alpha/2}\lambda}{\sqrt{n}}, \hat{\lambda} + \frac{q_{\alpha/2}\lambda}{\sqrt{n}} \right]$ be used as an asymptotic confidence interval for λ ?

Three “solutions”

1. The conservative bound: we have no a priori way to bound λ
2. We can solve for λ :

$$|\hat{\lambda} - \lambda| \leq \frac{q_{\alpha/2}\lambda}{\sqrt{n}} \iff \lambda \left(1 - \frac{q_{\alpha/2}}{\sqrt{n}}\right) \leq \hat{\lambda} \leq \lambda \left(1 + \frac{q_{\alpha/2}}{\sqrt{n}}\right)$$
$$\iff$$

It yields

$$\mathcal{I}_{\text{solve}} =$$

3. Plug-in yields

$$\mathcal{I}_{\text{plug-in}} =$$

95% asymptotic CI for the Kendall T example

Assume that $n = 64$ and $\bar{T}_n = 6.23$ and $\alpha = 5\%$.

We get the following confidence intervals of asymptotic level 95%:

- ▶ $\mathcal{I}_{\text{solve}} = [0.13, 0.21]$
- ▶ $\mathcal{I}_{\text{plug-in}} = [0.12, 0.20]$

Meaning of a confidence interval

Take $\mathcal{I}_{\text{plug-in}} = [0.12, 0.20]$ for example. What is the meaning of “ $\mathcal{I}_{\text{plug-in}}$ is a confidence intervals of asymptotic level 95%”.

Does it mean that

$$\lim_{n \rightarrow \infty} \mathbb{P}(\lambda \in [0.12, 0.20]) \geq .95?$$

There is a *frequentist* interpretation⁵:
If we were to repeat this experiment (collect 64 observations) then λ would be in the resulting confidence interval about _____ of the time (image credit: openintro.org).

⁵The frequentist approach is often contrasted with the Bayesian approach.

Hypothesis testing

How to board a plane?

The data

We collected data from two different airlines: JetBlue (R2F) and United (WilMA).

We got the following results:

| | R2F | WilMA |
|-----------------|------|-------|
| Average (mins) | 24.2 | 15.9 |
| Std. Dev (mins) | 2.1 | 1.3 |
| Sample size | 72 | 56 |

Model and Assumptions

- ▶ Let X (resp. Y) denote the boarding time of a random JetBlue (resp. United) flight.
- ▶ We *assume* that $X \sim \mathcal{N}(\mu_1, \sigma_1^2)$ and $Y \sim \mathcal{N}(\mu_2, \sigma_2^2)$
- ▶ Let n and m denote the JetBlue and United sample sizes respectively.
- ▶ We have X_1, \dots, X_n independent copies of X and Y_1, \dots, Y_m independent copies of Y .
- ▶ We further assume that the two samples are independent.

We want to answer the question:

Is $\mu_1 = \mu_2$ or is $\mu_1 > \mu_2$?

By making **modeling assumptions**, we have reduced the number of ways the hypothesis $\mu_1 = \mu_2$ may be rejected. We do not allow that $\mu_1 < \mu_2$!

We have two samples: this is a

A first heuristic

Simple heuristic:

“If $\bar{X}_n > \bar{Y}_m$, then $\mu_1 > \mu_2$ ”

This could go wrong if I randomly pick only full flights in my sample X_1, \dots, X_n and empty flights in my sample Y_1, \dots, Y_m .

Better heuristic: If

$\bar{X}_n -$ $> \bar{Y}_m +$
then $\mu_1 > \mu_2$ ”

To make this intuition more precise, we need to take the size of the random fluctuations of \bar{X}_n and \bar{Y}_m into account!

Waiting time in the ER

- ▶ The average waiting time in the Emergency Room (ER) in the US is 30 minutes according to the CDC
- ▶ Some patients claim that the new Princeton-Plainsboro hospital has a longer waiting time. Is it true?
- ▶ Here, we collect only one sample: X_1, \dots, X_n (waiting time in minutes for n random patients) with unknown expected value $\mathbb{E}[X_1] = \mu$.
- ▶ We want to know if $\mu > 30$.

This is a

Heuristic

Heuristic: If

$$\bar{X}_n$$

then conclude that $\mu > 30''$

Example 1

According to a survey conducted in 2017 on 4,971 randomly sampled Americans, 32% report to get at least some of their news on Youtube. Can we conclude that at most a third of all Americans get at least some of their news on Youtube?

- ▶ $n = 4,971$, $X_1, \dots, X_n \stackrel{iid}{\sim} \text{Ber}(p)$;
- ▶ $\bar{X}_n = 0.32$
- ▶ If it was true that $p = .33$: By CLT,

$$\sqrt{n} \frac{\bar{X}_n - .33}{\sqrt{.33(1 - .33)}} \approx \mathcal{N}(0, 1).$$

- ▶ $\sqrt{n} \frac{\bar{X}_n - .33}{\sqrt{.33(1 - .33)}} \approx -1.50$
- ▶ Conclusion:

The Standard Gaussian distribution

Example 2

Example 2: A coin is tossed 30 times, and Heads are obtained 13 times. Can we conclude that the coin is significantly unfair ?

- ▶ $n = 30, X_1, \dots, X_n \stackrel{iid}{\sim} \text{Ber}(p);$
- ▶ $\bar{X}_n = 13/30 \approx .43$
- ▶ If it was true that $p = .5$: By CLT,

$$\sqrt{n} \frac{\bar{X}_n - .5}{\sqrt{.5(1 - .5)}} \approx \mathcal{N}(0, 1).$$

- ▶ Our data gives $\sqrt{n} \frac{\bar{X}_n - .5}{\sqrt{.5(1 - .5)}} \approx$
- ▶ The number $-.77$ realization of a random variable $Z \sim \mathcal{N}(0, 1)$.
- ▶ Conclusion:

Statistical formulation

- ▶ Consider a sample X_1, \dots, X_n of i.i.d. random variables and a statistical model $(E, (\mathbb{P}_\theta)_{\theta \in \Theta})$.
- ▶ Let Θ_0 and Θ_1 be disjoint subsets of Θ .
- ▶ Consider the two hypotheses:
$$\begin{cases} H_0 : & \theta \in \Theta_0 \\ H_1 : & \theta \in \Theta_1 \end{cases}$$
- ▶ H_0 is the *null hypothesis*, H_1 is the .
- ▶ If we believe that the true θ is either in Θ_0 or in Θ_1 , we may want to *test H_0 against H_1* .
- ▶ We want to decide whether to *reject H_0* (look for evidence against H_0 in the data).

Asymmetry in the hypotheses

- ▶ H_0 and H_1 do not play a symmetric role: the data is only used to try to disprove H_0
- ▶ In particular lack of evidence, does not mean that H_0 is true (“innocent until proven guilty”)
- ▶ A *test* is a statistic $\psi \in \{0, 1\}$ such that:
 - ▶ If $\psi = 0$, H_0 is not rejected;
 - ▶ If $\psi = 1$, H_0 is rejected.
- ▶ Kiss example: $H_0: p = 1/2$ vs. $H_1: p \neq 1/2$.
- ▶ $\psi = \mathbb{I}\left\{ \right\}$, for some $C > 0$.
- ▶ How to choose the *threshold* C ?

Errors

- *Rejection region* of a test ψ :

$$R_\psi = \{x \in E^n : \psi(x) = 1\}.$$

- *Type 1 error* of a test ψ (rejecting H_0 when it is actually true):

$$\begin{aligned} \alpha_\psi &: \Theta_0 \rightarrow \mathbb{R} \\ \theta &\mapsto \mathbb{P}_\theta[\psi = 1]. \end{aligned}$$

- *Type 2 error* of a test ψ (not rejecting H_0 although H_1 is actually true):

$$\begin{aligned} \beta_\psi &: \Theta_1 \rightarrow \mathbb{R} \\ \theta &\mapsto \end{aligned}$$

- *Power* of a test ψ :

$$\pi_\psi = \inf_{\theta \in \Theta_1} (1 - \beta_\psi(\theta)).$$

Level, test statistic and rejection region

- ▶ A test ψ has *level* α if

$$\alpha_{\psi}(\theta) \leq \alpha, \quad \forall \theta \in \Theta_0.$$

- ▶ A test ψ has *asymptotic level* α if

$$\alpha_{\psi}(\theta) \leq \alpha, \quad \forall \theta \in \Theta_0.$$

- ▶ In general, a test has the form

$$\psi = \mathbb{I}\{T_n > c\},$$

for some statistic T_n and threshold $c \in \mathbb{R}$.

- ▶ T_n is called the *test statistic*. The rejection region is $R_{\psi} =$.

One-sided vs two-sided tests

We can refine the terminology when $\theta \in \Theta \subset \mathbb{R}$ and H_0 is of the form

$$H_0 : \theta = \theta_0 \quad \Leftrightarrow \quad \Theta_0 = \{\theta_0\}$$

- ▶ If $H_1 : \theta \neq \theta_0$: **two-sided test**
- ▶ If $H_1 : \theta > \theta_0$ or $H_1 : \theta < \theta_0$: **one-sided test**

Examples:

- ▶ Boarding method:
- ▶ Waiting time in the ER:
- ▶ The kiss example:
- ▶ Fair coin:

One or two sided tests will have different rejection regions.

Bernoulli experiment

- ▶ Let $X_1, \dots, X_n \stackrel{iid}{\sim} \text{Ber}(p)$, for some unknown $p \in (0, 1)$.
- ▶ We want to test:

$$H_0: p = 1/2 \text{ vs. } H_1: p \neq 1/2$$

with asymptotic level $\alpha \in (0, 1)$.

- ▶ Let $T_n = \left| \sqrt{n} \frac{\hat{p}_n - 0.5}{\sqrt{.5(1 - .5)}} \right|$, where \hat{p}_n is the MLE.
- ▶ If H_0 is true, then by CLT,

$$\mathbb{P}[T_n > q_{\alpha/2}] \xrightarrow{n \rightarrow \infty} 0.05$$

- ▶ Let $\psi_\alpha = \mathbb{I}\{T_n > q_{\alpha/2}\}$.

Examples

For $\alpha = 5\%$, $q_{\alpha/2} = 1.96$ and $q_{\alpha/2} =$

Fair coin

H_0 is at the asymptotic level 5% by the test $\psi_{5\%}$.

News on Youtube

$H_0 : p \geq 0.33$ vs. $H_1 : p < 0.33$. This is a -sided test.

We reject if:

$$\sqrt{n} \frac{\hat{p}_n - p}{\sqrt{p(1-p)}} > c$$

But what value for $p \in \Theta_0 =$ should we choose?

Type 1 error is the function $p \mapsto \mathbb{P}_p[\psi = 1]$. To control the level we need to find the p that **maximizes** it over Θ_0

→ no need for computations, it's clearly $p =$

H_0 is at the asymptotic level 5% by the test $\psi_{5\%}$.

p-value

Definition

The (asymptotic) *p-value* of a test ψ_α is the smallest (asymptotic) level α at which ψ_α rejects H_0 . It is random, it depends on the sample.

Golden rule

$\text{p-value} \leq \alpha \Leftrightarrow H_0$ is rejected by ψ_α , at the (asymptotic) level α .

The smaller the p-value, the more confidently one can reject H_0 .

Exercise: Cookies⁶

Students are asked to count the number of chocolate chips in 32 cookies for a class activity. They found that the cookies on average had 14.77 chocolate chips with a standard deviation of 4.37 chocolate chips. The packaging for these cookies claims that there are at least 20 chocolate chips per cookie. One student thinks this number is unreasonably high since the average they found is much lower. Another student claims the difference might be due to chance. What do you think (compute a p-value)?

⁶from the textbook OpenIntro Statistics

Exercise: kiss

Recall that in the Kiss example we observed 80 out of 124 couples turning their head to the right. Formulate the statistical hypothesis problem, compute the p-value and conclude.

Exercise : Machine learning predicts breast cancer

A vast problem in breast cancer are false positive, that is surgery performed on benign tumors. A new machine learning procedure claims to improve the state-of-the art (95% of false positive) significantly while preserving the same true positive rate (detecting malignant tumors as malignant). To verify this claim, we collected data on 297 benign tumors. The algorithm recommended to perform surgery on 206 of them.

Let p denote the proportion of benign tumors on which the algorithm prescribes surgery.

Formulate the statistical hypothesis problem, compute the p-value and conclude.

Recap

- ▶ A statistical model is a pair of the form $(E, (\mathbb{P}_\theta)_{\theta \in \Theta})$ where E is the sample space and $(\mathbb{P}_\theta)_{\theta \in \Theta}$ is a family of candidate probability distributions.
- ▶ A model can be well specified and identifiable.
- ▶ The trinity of statistical inference: estimation, confidence intervals and testing
- ▶ Estimator: one value whose performance can be measured by consistency, asymptotic normality, bias, variance and quadratic risk
- ▶ Confidence intervals provide “error bars” around estimators. Their size depends on the confidence level
- ▶ Hypothesis testing: we want to ask a yes/no answer about an unknown parameter. They are characterized by hypotheses, level, power, test statistic and rejection region. Under the null hypothesis, the value of the unknown parameter becomes known (no need for plug-in).
