Problem Set

Problem Set due May 03, 2016 at 17:00 UTC 

1. ANOVA is an appropriate statistical measure when we want to:

(1/1 point)

- ☐ determine whether the hypothesized mean in one population is the same for two or more other populations.
- ☒ compare the means of three or more populations at once. 
- ☐ estimate the size of the difference between two or more group means.
- ☐ compare the distributions of two or more categorical variables.

2. In ANOVA, we calculate an F statistic. The F statistic is the ratio of:

(1/1 point)

- ☐ the difference in group means compared to the expected group difference in means.
- ☐ the variation in one group compared to the variation in the other.
- ☐ the variation within groups to the total variation.
- ☒ the variation between groups to the variation within groups. ✓

3. If the null hypothesis for an ANOVA test is $\mu_A = \mu_B = \mu_C$, what is the appropriate alternative hypothesis?

(1/1 point)

- ☐ $\mu_A \neq \mu_B \neq \mu_C$
- ☒ At least one of the means is different. ✓

☐ $\mu_A \neq \mu_B$ or $\mu_A \neq \mu_C$

4. The source table below presents the results from an ANOVA comparing four treatment conditions with $n=25$ participants in each condition. Compare all the missing values. *Hint: Start with degrees of freedom.* (Round to 3 decimal places where needed.)

Source	SS	df	MS	F-statistic	F-critical
Between	[SS _B]	[df _B]	19	F-stat	2.699
Within	[SS _W]	[df _W]	[MS _W]		
Total	117	[df _T]			

(7/7 points)

4a. $SS_B =$

Answer: 57

4b. $SS_W =$

Answer: 60

4c. $df_B =$

Answer: 3

4d. $df_W =$

Answer: 96

4e. $df_T =$

Answer: 99

4f. $MS_W =$

Answer: .625

4g. F-stat=

Answer: 30.400

(1/1 point)

4h. We should _____ the null hypothesis.

Answer: Reject

(1/1 point)

4i. Assume your F-statistic is significant, suggesting that at least one treatment condition is different from the others. How many post-hoc group comparisons will you need to run?

Remember the formula for group comparisons: $\frac{k(k-1)}{2}$

☒ 6 ✓

☐ 15

☐ 10

☐ 12

(1/1 point)

4j. Using the Bonferroni correction, what significance level should you use for each post-hoc hypothesis test if you want an overall significance level of 0.05?

☐ .050

☐ .100☒ .008 ✓☐ .003

(1/1 point)

4k. What was the overall risk of making a Type I error in this ANOVA? (*Round to 2 decimal places.*)

 ✓

Answer: .05

(1/1 point)

4l. What would the risk of a Type I error have been if you had run multiple t-tests instead? Assume $\alpha = 0.05$ for each test. (Round to 2 decimal places)

Hint: $1 - (1 - \alpha)^C$

0.26

Answer: .26

0.26

(1/1 point)

4m. How would you interpret this difference in overall Type I error rate?

- ☐ The risk of missing a significant difference between means, when one really exists, is 5 times lower when you run an ANOVA.
- ☒ The risk of finding a difference between group means, when one does not really exist, is 5 times lower when you run an ANOVA. ✓
- ☐ The risk of falsely rejecting the null hypothesis is higher when you run an ANOVA.
- ☐ The risk of falsely failing to reject the null hypothesis is higher when you run multiple t-

tests.
