Homework Problem: Alternate-Reality Potter Family Tree

10/10 points (graded)

Consider the family tree below, which shows three generations of the Potter family. In this alternate reality, everyone only has one parent. X_1 is the parent of X_2 and X_3 , X_2 is the parent of X_4 and X_5 , and X_3 is the parent of X_6 and X_7 .

Each person can be either a wizard, who can perform magic, or a muggle, who cannot. If a member of the family is a wizard, his or her children have a **50%** chance of inheriting his magical abilities, and they are muggles otherwise. A muggle has **25%** chance of having wizard children. Suppose you are the person at node X_4 .

Week 7: Special Case - MAP Estimation in Hidden Markov Models

- **(a)** Let each variable X_i take one of two states: "wizard" or "muggle." You know you are a wizard, but you don't know anything about the rest of your relatives in the tree. We define ϕ_{wiz} and ϕ_0 as follows:

		$\phi_{\text{wiz}}(x)$	$\phi_0(x)$
x	wizard	1	1
	muggle	0	1

The joint distribution can be represented by this graph with the node potentials defined as $\phi_i(x_i) = \phi_0(x_i)$ for $i \in \{1, 2, 3, 5, 6, 7\}$, and $\phi_4(x_4) = \phi_{\text{wiz}}(x_4)$.

All the edge potentials can be chosen so that they are the same function $\psi(\cdot, \cdot)$, where the first argument is always the parent value and the second argument is always the child value. Determine such a function ψ .

Please provide the **exact** answer for these four quantities.

$$\psi(\text{wizard}, \text{wizard}) = \boxed{0.5} \quad \checkmark$$

$$\psi(\text{wizard}, \text{muggle}) = \boxed{0.5} \quad \checkmark$$

$$\psi(\text{muggle}, \text{wizard}) = \boxed{0.25} \quad \checkmark$$

$$\psi(\text{muggle}, \text{muggle}) = \boxed{0.75} \quad \checkmark$$

- **(b)** Evaluate the messages $m_{2 \rightarrow 1}(\cdot)$ and $m_{3 \rightarrow 1}(\cdot)$ according to the sum-product algorithm, expressing your answers in the form of tables.

For each message table, please normalize the entries so that they add to 1.

(Please be precise with at least 3 decimal places, unless of course the answer doesn't need that many decimal places. You could also put a fraction.)

$$m_{2 \rightarrow 1}(\text{wizard}) = \boxed{0.5454545454545455} \quad \checkmark$$

$$m_{3 \rightarrow 1}(\text{wizard}) = \boxed{0.5} \quad \checkmark$$

- (c) Determine the probability that your grandparent, X_1 , was a wizard.

(Please be precise with at least 3 decimal places, unless of course the answer doesn't need that many decimal places. You could also put a fraction.)

- (d) We now extend the tree from 3 generations to n generations. Every parent continues to have exactly two children, so there are 2^{k-1} individuals in the k th generation. In this larger tree, you continue to be in the last (i.e., n th) generation.

Before knowing whether or not you are a wizard, you use the sum-product algorithm to find the probability that the earliest ancestor (the root) was a wizard.

Then, you discover that you are a wizard, but know nothing about the rest of your relatives. In order to determine the probability that your earliest ancestor (the root) is a wizard given this information, how many messages must be recomputed?

Provide your answer in terms of n .

In this part, please provide your answer as a mathematical formula (and not as Python code). Use \wedge for exponentiation, e.g., x^2 denotes x^2 . Explicitly include multiplication using $*$, e.g. $x*y$ is xy .

What's the trick in Potter b

discussion posted 2 days ago by **RobertOstas**

Hello,

I got right answers in part a and right answer for $m_{3 \rightarrow 1}(W)$ in part b. However my answer for $m_{2 \rightarrow 1}(W)$ in part b is not correct.

I...

in part (d) where does n start to count?

question posted 4 days ago by **myjy**

if n starts from 0 the answer will change.

nice question

discussion posted 3 days ago by **SamS2**

A nice question. The language used here:

"A muggle has 25% chance of having wizard children."

could be tightened up.

What is one message?

question posted a day ago by **PavelKrupets**

When asked how many messages needed to be recalculated I entered number of messages for each RV value. Like: $m_{21}(w)$, $m_{21}(m)$.

I assume that is wrong and one message is $m_{21}(.)$?

2 messages for an edge: one forward and one backward. But we use only one direction.

I modeled it in my head for a 3 node network then 4 and 5 at which point I had an answer to test. And it worked.
