## QUESTION 12 (1 point possible)

When assessing the residuals of a regression model you observe the following:

- Residuals exhibit a persistent structure and are not randomly distributed with respect to values of the label or the features.
- The Q-Q normal plots of the residuals show significant curvature and the presence of outliers.

Given these results, which two of the following things should you try to improve the model?

☐ Cross validate the model to ensure that it will generalize properly.

☒ Try a different class of regression model that might better fit the problem should be tried.

☐ Create some engineered features with behaviors more closely tracking the values of the label.

☒ Add a **Sweep Parameters** module with the **Metric for measuring performance for classification** property set to *Accuracy*.

Note: Make sure you select all of the correct options—there may be more than one!
