## MO2.4

The basic philosophy of the numerical methods we will study for solving IVPs is to start from a known initial state,  $\underline{u}\left(t_{I}\right)=\underline{u}_{I}$ , and somehow approximate the solution a small time forward,  $\underline{u}\left(t_{I}+\Delta t\right)$  where  $\Delta t$  is a small time increment. Then, we repeat this process and move forward to the next time to find an approximation to  $\underline{u}\left(t_{I}+2\Delta t\right)$ , and so on. This is known as discretizing the solution, as we have moved from representing infinitely many times t, i.e. all t from  $t_{I}$  to  $t_{F}$  to a representation at a discrete (i.e. finite) set of time points. This discrete representation is shown in Figure 8.12. In the limit as  $\Delta t \rightarrow 0$ , the discrete solution representation approaches the exact solution.
